Python 3 Notebook Execution Output

In [1]:

```
X = 100
Y = 29

Tot = X + Y
multiplied_result = Tot * 3
final_result = multiplied_result ** 2

print("The result of the calculation was:")
print(f"\t{final_result}")
```

OUTPUT:

```
The result of the calculation was:
        149769
```

In [2]:

```
# 1. Take inputs from the user with the correct data types
name = input("Name:")
year_of_birth = int(input("Year of birth: "))
age = int(input("Age: "))

# 2. Extract the password components
# Get the last two digits of the year (converted to string)
year_part = str(year_of_birth)[-2:]

# Get the first 3 letters of the name
name_part = name[:3]

# Calculate the 2nd power of the age (age squared, converted to string)
age_part = str(age ** 2)

# 3. Combine all parts into the final password string
password = year_part + name_part + age_part

# 4. Print the output
print("Password:", password)
```

OUTPUT:

```
Name:  John
Year of birth:  1995
Age:  26
Password: 95Joh676
```

In [3]:

```
# 1. Ask the user for two integers
num1 = int(input("First number: "))
num2 = int(input("Second number: "))

# 2. Check the condition using if-elif-else and the modulo operator (%)
if num1 % 2 == 0 and num2 % 2 == 0:
    print("Both numbers are even.")
elif num1 % 2 == 0 or num2 % 2 == 0:
    print("One of the numbers is even.")
else:
    print("Both numbers are odd.")
```

OUTPUT:

```
First number:  5
Second number:  6
One of the numbers is even.
```

In [4]:

```
# Ask the user for an integer
num = int(input("Give an integer: "))

# Calculate the sum of all numbers from 0 up to (but not including) the input
total_sum = sum(range(num))

# Print the result
print(f"The sum was: {total_sum}")
```

OUTPUT:

```
Give an integer:  5
The sum was: 10
```
